

Priority Probes

In your probe properties there is an “override” checkbox. Any probe marked as "override" will completely replace any probe it overlaps with that is not marked "override" instead of blending with it. This is essential for allowing dynamic probes to move through the space already lit by other probes without the other probes' light leaking in. It can also be used to add localized "detail" probes to an area. However, the practice of using these as detail probes, especially large ones that can cover lots of screen space, should be used sparingly and carefully considered, since there is a performance cost.

An override probe will prevent probes beneath it from applying and costing as much as full probe overdraw. However, the presence of other probes underneath the override probe will still cause the shader to consider evaluating those probes. In the case where it pushes the shader from 1 "visible" probe to 2, or from 2 to 3 or more, it will switch to a slower, slightly less efficient shader. This cost is significantly less than adding cut-out boxes to parent probes or full overdraw, so in most cases it's still worth it. But it shouldn't become common practice to use override probes on every surface.
