

Probe Geometry Change Tracking

This feature tracks probe edits and watches for geometry changes around the probes between sessions.

When you check for geometry changes, it looks to see if there is still geometry in those locations. These points are remembered even if you adjust the face slightly after clicking, but if you place a face manually without Alt+Clicking there's nothing to track. In other words it has a good chance of being able to point you to areas in a map that need probe maintenance, however it is not guaranteed to catch all changes.

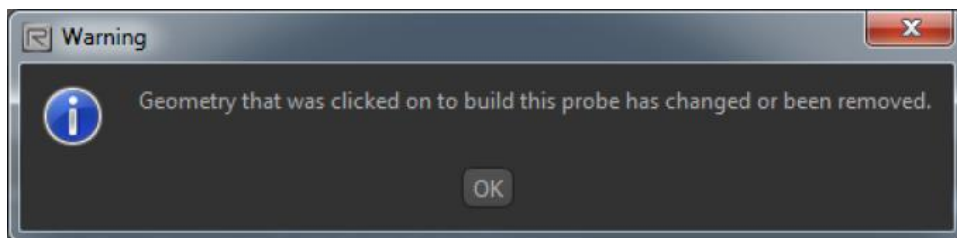

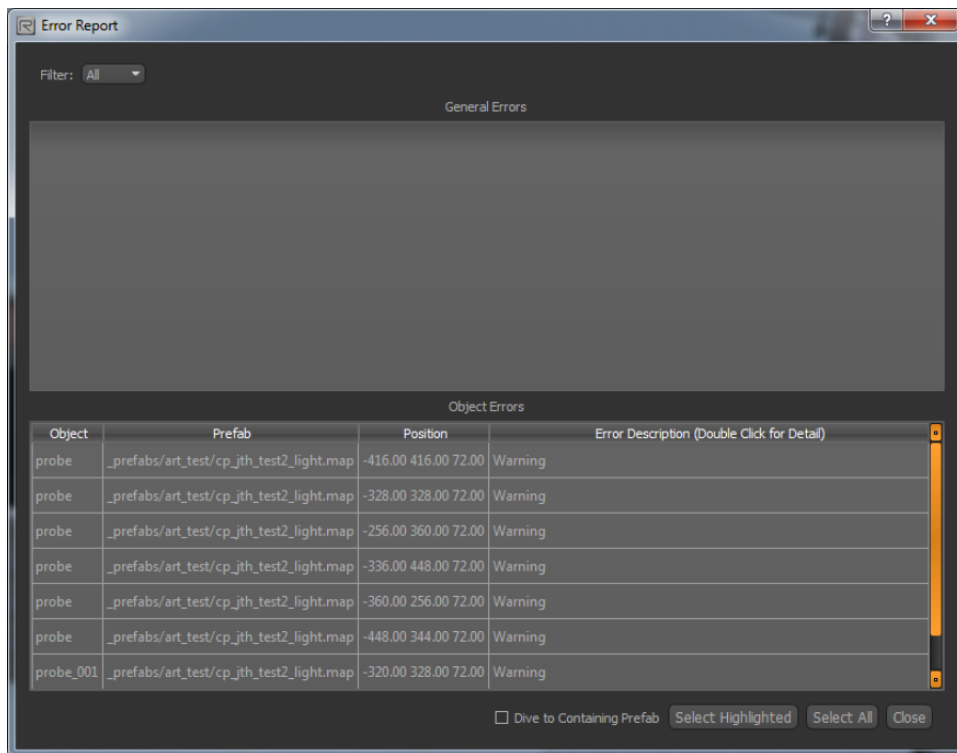

Check Probe Geometry Changes can be found under the View->Debug->Reflection Probes menu. Any of these options can be assigned to key press shortcuts. The options are:

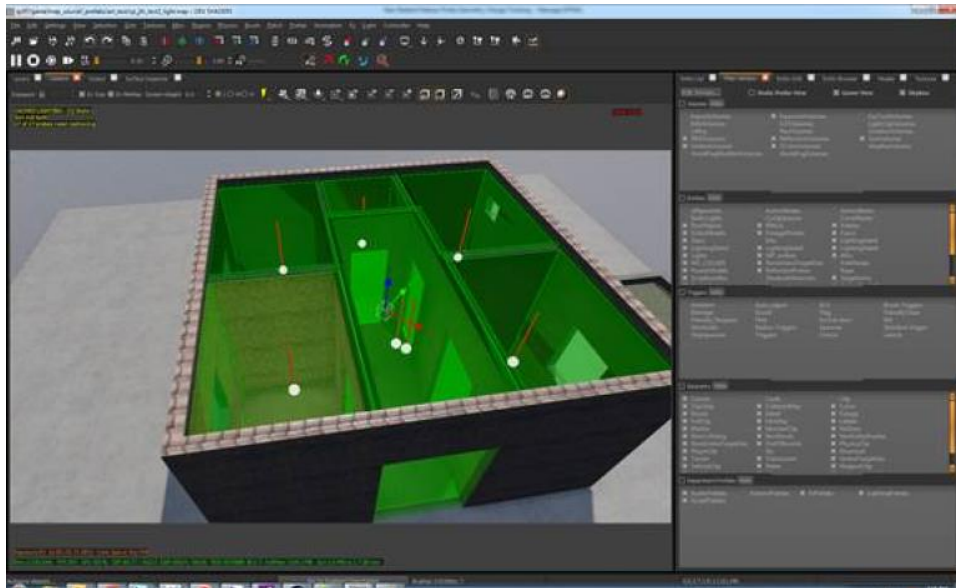

- **Check Probe Geometry Changes** – Run a test on every probe in the entire map looking for changes to nearby geometry and pop up a warning report if any are found.
- **Approve Selected Probe Changes** – Delete the tracking data that appears invalid on the selected probe(s), so the probe will no longer show up in the warning report.
- **Generate Probe Geometry Data** – Synthesize click data on the selected probes.

Check Probe Geometry Changes

This function can be run from the top level map and will search through all prefabs looking for probes with potential changes. It will pop up a report like the one below. These probes can be selected one at a time for checking, or if the report takes a long time you can select all of them and save the list in the Entity Property Table so you can work on them individually without having to re-run the list. This will only catch changes where the geometry that was clicked on has been moved or removed. That means if something else has been put in front of it, or there are new holes or dips in the wall but not at the point that was clicked on, it won't catch the changes. It's just a starting point.

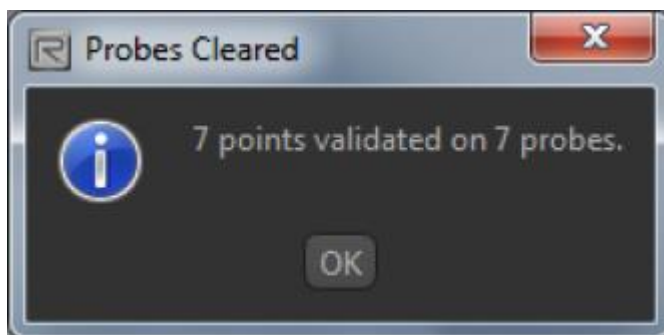

Once the probes have been selected, the areas of the probe that caused the warning will be indicated by a red line from the center of the probe to the click point that's no longer valid. This is useful as sometimes the changes are hard to spot and this will point you to exactly where to look.

Approve Selected Probe Changes

If you find changes and address them by Alt+Clicking again to reposition the face in question, the probes will no longer warn about changes. You can tell this is happening because the red warning line will disappear immediately when you replace its click data. However if you decide the changes don't matter, or you repair them by manually sliding a face, the probe will continue to come up in the warning report because it still has the offending data. This option in the menu will delete this data from the selected probe, but will leave any data on the probe that is still valid. It makes sense to choose this option when viewing a probe from the warning report that you don't wish to change at all, as that warning no longer serves a purpose and the probe can still warn if walls on other sides move.

Generate Probe Geometry Data

In case you have a probe that doesn't have data, this option will look at every face on every probe and try to find a surface that exactly matches it. If it finds one, it will save a fictional click point.

However, it is not guaranteed to generate points for every face, even if there is a wall right there, because it may end up checking points that just happen to be obscured or missing. This can take

some time and a progress bar will pop up while it's running, but you should only have to run it once. Don't forget to save afterward!
